Valid Vault Enterprise Plan

Nov 12, 2026 · Michael Carter

Overview

Valid Vault Enterprise gives every employee the company logins their job needs, and the admin controls which people and devices can use them. Logins stay on equipment the company already owns. The company runs no password server, no database, and no vendor-hosted vault.

The personal Valid Vault ships today on Chrome, Brave, and Edge, with Android in Google Play testing. Valid Vault Enterprise is designed in detail and not yet built.

It is for businesses that answer for where their data sits: medical offices, law and accounting firms, banks and credit unions, defense suppliers, utilities, and government offices.

What the business gets

The admin decides who uses each set of company logins. Employees unlock Valid Vault with a password or fingerprint and fill the logins assigned to them.

- **Shared company vaults:** company logins stored as encrypted files on the company's own file server or NAS
- **Access by person and device:** the admin adds and removes members and decides which devices get which shared vaults
- **Enrollment by short code:** a new device shows a code, and the admin checks it before approving the device
- **Departures:** removing a device re-keys every shared vault it could open, so it never receives anything saved afterward
- **Multi-executive approval:** each company picks which sensitive actions, such as ownership changes or admin recovery, need signatures from several executives
- **Device-signed changes:** every change is signed by the device that wrote it, so each change traces to a device
- **Company-signed settings:** rules and policies are signed with the company's key and pushed through the device management it already uses

Planned for phase 2: fill-only devices

Employees on IT-managed devices fill logins without being able to view or copy the passwords. This is planned and not built. It needs its own security work and testing. Turning off developer tools by Chrome policy is one part of it and is no guarantee on its own.

Deployment choices

Each company sets these in its signed company settings. Each one trades employee convenience against tighter control over where logins can be used and stored.

Setting	Choices
Shared vault storage	A local encrypted copy that works away from the office, or network only, where shared logins work only on the office network or VPN
Personal vaults	An encrypted personal folder on the company drive, or no personal vault on company laptops
Repeated wrong unlocks	Wipe the local vault and device key after a set number of wrong tries, or leave it off
Laptop protection	BitLocker required on company laptops, listed on the deployment checklist

How the architecture works

Device and vault keys. Each device makes its own key pair, protected by that device's existing unlock. Each shared vault key is encrypted separately to every member device, and a device opens the shared vault only by unwrapping its own copy.

Company authority. The company's signing key signs the settings and every membership change. Devices refuse settings or member lists that are unsigned or older than what they already hold. Executive approvals use each executive's own signing key, with a threshold the company sets.

Shared storage. Encrypted vault files and the signed member list sit on the company's file server or NAS. The extension never contacts any Valid Vault service. It does need the office network or VPN to reach the file share.

Recovery. A separate recovery key is split among trusted people, such as any 3 of 5. Recovery restores admin access after a lost admin device. Executive approval authorizes sensitive actions. They are separate mechanisms.

Compound Questions, shipping today. The encrypted key backup file is locked under a passphrase plus three Compound Questions. All four are joined into one secret and run through 1,000,000 rounds of PBKDF2-SHA256, so a guess must get all four right at once. A passphrase narrowed to 1 million candidates falls in about 2 minutes on its own. Add three answers with about 1,000 plausible values each, and the same search takes about 3,600 years on one high-end graphics card.

Stolen laptops. BitLocker, network-only storage, and prompt removal limit what a thief gets. A laptop that already held a local copy keeps that snapshot, locked by the master password, until it is wiped. Re-keying blocks everything saved afterward and cannot erase what a device already holds, so passwords that laptop could open should be changed.

The Security Design in this packet covers each mechanism, its limits, and the tests behind it.

How it fits with your existing IT

Valid Vault runs on the tools a company's IT already uses. Device management pushes the extension and its signed settings, BitLocker protects laptops, and the file server or NAS holds the encrypted vault files. What those tools don't manage is the logins themselves, especially logins to outside sites such as the bank, payroll, insurance carriers, and vendors.

IT already handles	Valid Vault adds
Which devices are trusted, through Intune, Group Policy, or Chrome management	Which trusted devices can open which shared logins
Who can reach a folder, through file permissions	Encryption, so file server, backup, and support accounts see only scrambled files
Wiping or disabling a departed employee's device	Re-keying, so a removed device can't read anything saved afterward

IT already handles	Valid Vault adds
Pushing policy from an admin account	Settings and membership changes signed with the company key, plus several executives' signatures where the company requires them

How it compares

Option	Server to run	Each person has their own access	Removing one person
Spreadsheet on the shared drive	None	No	Change folder permissions. Any copy they made stays readable
KeePass file on the shared drive	None	No. Everyone shares one master password	Change the shared master password and give it to everyone else
Bitwarden self-hosted, Enterprise plan	Yes: servers, Docker, a database, and a TLS certificate	Yes	Remove them in the admin console
Valid Vault Enterprise	None. Uses the existing file server or NAS	Yes, per device	Remove the device, and its shared vaults get a new key

Valid Vault gives each person their own access and clean removal, which a shared KeePass file lacks, without the server that self-hosted Bitwarden requires. Companies comfortable with a cloud vault are already well served by hosted products. Valid Vault is for the ones that want their logins on their own equipment and have no one to run a server.

Available now and what gets built

Live today: Valid Vault Personal. Chrome, Brave, and Edge extensions, plus Android in Google Play testing.

Phase 1: shared company vaults. Built in nine stages. A stage closes only when its acceptance tests pass.

- **Stage 0, feasibility:** prove shared-folder reads and writes from the extension on Chrome, Edge, and Brave, over a mapped drive and a NAS
- **Stage 1, crypto foundation:** device keys, key wrapping, signing, and the recovery split
- **Stage 2:** company identity and signed settings
- **Stage 3:** enrollment and authorization rules
- **Stage 4:** shared vault storage and merging
- **Stage 5:** removal, re-keying, and recovery
- **Stage 6:** the Organization tab in Manage
- **Stage 7:** phones and deployment packages
- **Stage 8:** security review and the first pilot

Phase 2: IT-managed devices. Managed setup and fill-only access.

Phase 3: audit and reporting. Audit reports, admin reporting, and a departure checklist.

Stage 0 is ready to start. The Phase 1 Build Plan in this packet has the tasks, formats, tests, and estimates for each stage.

Pricing

Licenses are $7 per user per month, billed yearly. The personal Valid Vault stays free.

Business size	Setup fee (estimate)
Small	$299
Mid-size	$599
Large	$999

Setup covers configuration and first deployment, and adjusts with each business's size and complexity.

Team and go-to-market

The founder builds the product. A contract sales lead is paid on commission. A contract outreach lead covers Africa, with a university partnership being explored. Overseas support contractors are added as customers sign, and one engineer is hired in year 3.

The sales lead works with any business that shares logins, from small offices and family shops to growing companies with many staff, and even medical practices, law firms, and credit unions that answer to regulators and regular audits. Each pilot is meant to become a reference customer.

In this packet

- **Valid Vault Enterprise Plan:** this document
- **Valid Vault Enterprise Security Design:** threat model, mechanisms, limits, and approved claims
- **Valid Vault Enterprise Phase 1 Build Plan:** stages, file formats, tasks, tests, and estimates
- **Valid Vault Enterprise Intake Form (sample):** what a business fills in before deployment

Financial projections and terms are shared on request.
